U.S. PROVISIONAL PATENT APPLICATION

METHOD OF IDENTIFYING HAIRPIN DNA PROBES BY PARTIAL FOLD ANALYSIS

BACKGROUND OF THE INVENTION

The use of DNA hairpins as molecular beacons, both in solution (Broude, Trends Biotechnol. 20:249-256 (2002); Dubertret et al., Nat. Biotechnol. 19:365-370 (2001)) and immobilized on a solid surface (Fang et al., J. Am. Chem. Soc. 121:2921-2922 (1999); Wang et al., Nucl. Acids. Res. 30:e61 (2002); Du et al., J. Am. Chem. Soc. 125:4012-4013 (2003)), has proven to be an excellent method for "label-free" detection (Chan et al., J. Am. Chem. Soc. 123:11797-11798 (2001)) of biological entities. This disclosure describes a new method of molecular beacon discovery which relies on the generation of naturally occurring hairpins. The method of discovery and its advantages shall be discussed herein.

The traditional method of molecular beacon generation is to supplement a naturally occurring DNA sequence at both the 5' and 3' ends with the necessary nucleotide composition to force the formation of a hairpin. This technique has a major flaw in that the introduction of nucleotides that are not specific for the intended target sequence increases the likelihood of non-specific binding. The use of naturally occurring DNA hairpins obviates this flaw by eliminating the need for supplementation of additional bases, the result: a probe that is completely specific for its designed target.

DESCRIPTION OF THE INVENTION

The method of the invention involves obtaining or providing a nucleotide sequence from a molecular target. The nucleotide sequence can be sequenced from an isolated cDNA or obtained from an online database such as GenBank. Regardless of the source of the nucleotide sequence, a partial fold analysis is performed on the nucleotide sequence using any of a variety of suitable folding software such as, e.g., RNAStructure program (available from D. Turner at the University of Rochester, Rochester, NY), Mfold software package (available from M. Zucker at the Rensselear Polytechnic Institute, Rensselear, NY), and Vienna RNA software package, including RNAfold, RNAeval, and RNAsubopt (available from I. Hofacker at the Institute for Theoretical Chemistry, Vienna Austria). The resulting folded structure may or may not be the true active conformation of the RNA molecule in a cellular environment; however, it represents the lowest free energy state as predicted using such software. It is believed that more often than not, the predicted lowest free energy state of the nucleic acid molecule sufficiently resembles the true active conformation. Nonetheless, the resulting folded structure is analyzed to identify hairpin regions thereof.

Having identified hairpin structures within the folded structure of the prospective target nucleic acid molecule, the hairpin sequences are isolated from the larger sequence (i.e., that was used as input to the folding software). The isolation can be performed in silico. Once isolated, the hairpin sequence is subjected to a second structural prediction as was performed on the prospective target nucleic acid molecule.

The overall length of the selected hairpin is preferably between about 12 and about 60 nucleotides, more preferably between about 20 and about 50 nucleotides, most preferably between about 30 and about 40 nucleotides. It should be appreciated, however, that longer or shorter nucleic acids can certainly be used. According to the preferred hairpins, the regions forming the stem of the hairpin are preferably at least about 4

nucleotides in length and up to about 28 nucleotides in length, depending on the overall length of the nucleic acid probe and the size of a loop region present between the portions forming the stem. It is believed that a loop region of at least about 4 or 5 nucleotides is need to form a stable hairpin. The regions forming the stem can be perfectly matched (i.e., having 100 percent complementary sequences that form a perfect stem structure of the hairpin conformation) or less than perfectly matched (i.e., having non-complementary portions that form bulges within a non-perfect stem structure of the hairpin conformation). When the first and second regions are not perfectly matched, the regions forming the stem structure can be the same length or they can be different in length.

Importantly, applicants have found that the predicted E value for the hairpin should preferably be at most about -3 kcal/mol, more preferably at most about -3.5 kcal/mol, most preferably between about -4 kcal/mol and about -12 kcal/mol. It should be appreciated, however, that identified hairpins can still function as molecular probes if their predicted E

value falls outside these ranges.

Once the structure of the hairpin itself has been predicted, the duplex formed between the hairpin and its complement is subjected to a structural prediction as was performed on the prospective target nucleic acid molecule and the hairpin. This step, not necessary for identification of the hairpin per se, is performed primarily to ensure that the hybridization of the two sequences (hairpin and complement), and thus the disruption of the hairpin, will be an energetically favorable process. Ideally, there should be an increase in the predicted E value, preferably at least about a two-fold increase, preferably at least about a five-fold increase, more preferably at least about a ten-fold increase. This structural prediction also serves to demonstrate the primary advantage of the technique: after hybridization, there are no extraneous unhybridized nucleotides and, thus, lowered risk of non-specific binding.

To further verify the specificity of the hairpin sequence for its complement, the hairpin sequence can be used to perform a BLAST database search (of, e.g., the GenBank database). Ideally, the resulting BLAST search will show not only high match scores for molecular targets (or target organisms), but also a sharp discrepancy (or clear demarcation) between the high match scores of the target and any match scores of nucleic acid molecules bearing lower similarity. By sharp discrepancy and clear demarcation, it is intended that a gap of at least about 5 points, preferably at least about 10 points, more preferably at least about 15 points, most preferably at least about 20 points, exists between the target and non-target sequences. This is exemplified in Example 1 below.

The probes identified in accordance with the present invention can be used in any of a variety of hybridization-based applications, typically though not exclusively detection procedures for identifying the presence in a sample of a target nucleic acid molecule. By way of example, uses of the probes are described in greater detail in U.S. Utility Patent Application to Miller et al., entitled "Hybridization-Based Biosensor Containing Hairpin Probes and Use Thereof," filed concurrently with this application and expressly incorporated by reference in its entirety.

Example 1 - Hairpins Targeted to Bacillus anthracis pag Gene

A partial gene sequence of the *Bacillus anthracis* Pag gene (isolate IT – Carb3 – 6254) (Adone et al., *J. Appl. Microbiol.* 92:1-5 (2002), which is hereby incorporated by reference in its entirety) was obtained from GenBank. The secondary structure of ~1000 nucleotide fragments of the aforementioned sequence were then computationally predicted (RNAstructure v. 3.7: Mathews et al., *J. Mol. Biol.* 288:911–940 (1999), which is hereby

incorporated by reference in its entirety). Ideally, the secondary structure of the entire sequence would be predicted, but it was discovered repeatedly that segments larger than approximately 1000 bases would crash the program RNAstructure v. 3.7.

An example of a large sequence structure prediction is shown in Figure 1 (below).

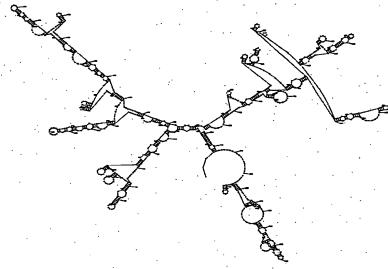

Figure 1. Secondary structure prediction of *B. anthracis* Pag gene 541 – 1560.

As is evidenced by Figure 1, the "folding" of large sequences of DNA reveals several naturally occurring hairpins. The sequences are then isolated from the full sequence and subjected to second structure prediction. Figures 2 and 3 show structural predictions for two of these excised sequences.

Figur 2. Pag 668 – 706
Eprodict = -4.4 kcal/mol
nt count = 39

Figur 3. Pag 1209 - 1241 E_{predict} = -4.7 kcal/mol nt c unt = 34

These natural hairpins both appear to be good candidates for use as a molecular beacon, because each contains between about 30 to about 40 nucleotides long and each has a E_{predict} between about -4 kcal/mol and about -12 kcal/mol.

Having confirmed that the selected hairpin(s) satisfy initial selected criteria, a final structural prediction of the sequence in duplex with its complement was computed (Figures 4 and 5). This last prediction was done primarily to ensure that the hybridization of the two DNA sequences, and thus the disruption of the hairpin will be an energetically favorable process. Each of these duplexes have a predicted E value that is about nine to tenfold greater than the predicted E value for the hairpin alone, and therefore they are expected to favorably form a duplex with their targets.

Figure 4. Pag 668 – 706 duplex E_{predict} = -43.2 kcal/mol

Figure 5. Pag 1209 – 1241 duplex E_{predict} = -42.6 kcal/mol

The specificity of the hairpin of Figure 2 for its target was supported by a BLAST search of the GenBank database using the Pag 668-704 sequence. The results of this BLAST search are shown below in Figure 6 below. In particular, the BLAST results indicate that only sequences from *Bacillus anthracis*, the target organism, have high scores; whereas other "matching sequences from non-target organisms have significantly lower scores. In this instance, a clear demarcation exists between target scores (of 78) and non-target scores (of 42 and lower). This demonstrates that this hairpin will be specific for its target.

Example 2 - Hairpins Targeted to Staphylococcus aureus Genome

Two DNA hairpins, AH2 and BH2 were designed to incorporate portions of the Staphylococcus aureus genome (Genbank Accession AP003131, which is hereby incorporated by reference in its entirety). The AH2 sequence appears to target an intergenic region between ORFID:SA0529 and ORFID:SA0530, and the BH2 sequence appears to target an intergenic region between ORFID:SA0529 and ORFID:SA0530 but including several bases within the latter open reading frame.

A segment of the complete Staphylococcus aureus genome was obtained from the GenBank database and the secondary structure of the obtained segment was predicted using computer program RNAStructure version 3.7 (Mathews et al., J. Mol. Biol. 288:911-940 (1999), which is hereby incorporated by reference in its entirety). From this predicted structure, two naturally occurring hairpins were identified, one corresponding to AH2 and the other corresponding to BH2.

Having identified these two sequences, these sequences were isolated from the larger sequence and subjected to a second structure prediction as described above. The predicted structure of AH2 is characterized by a predicted free energy value of about -6.1 kcal/mol and the predicted structure of BH2 is characterized by a predicted free energy value of about -3.5 kcal/mol. Both are within the size range of about 30-40 nucleotides.

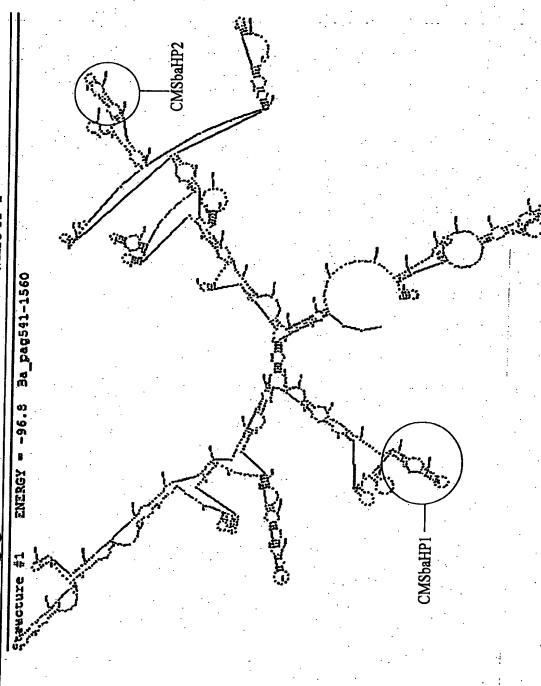

Figure 7 AH2 (E = -6.1) nt = 33

Figure 8 BH2 (E = -3.5 kcal/mol) nt = 37

Having selected AH2 and BH2, a final structural prediction of the duplexes (AH2 and BH2 with their respective complements) was carried out to determine their predicted E value. The duplex containing AH2 was predicted to have a free energy value of -38.3 kcal/mol and the duplex containing BH2 was predicted to have a free energy value of -39.0 kcal/mol. These values indicate that the hybridization between the hairpin and its target will be an energetically favorable process. A BLAST search was independently performed using the AH2 and BH2 sequences, the results indicating that only segments of the Staphylococcus aureus genome contain highly related nucleotide sequences.

This process described above and exemplified in Examples 1-2 has also been performed using *Exophiala dermatitidis* 18S ribosomal RNA gene sequences to identify hairpin probes that can be used to identify the target gene (and organism); *Trichophyton tonsurans* strain 18S ribosomal RNA gene sequences to identify hairpin probes that can be used to identify the target gene (and organism); and *Bacillus cereus* genomic DNA to identify hairpin probes that can be used to identify the target DNA (and organism).

Although preferred embodiments have been depicted and described in detail herein, it will be apparent to those skilled in the relevant art that various modifications, additions, substitutions, and the like can be made without departing from the spirit of the invention and these are therefore considered to be within the scope of the invention as defined in the claims which follow.

What is Claimed:

1. A method of identifying hairpin nucleic acid probes, the method comprising:

providing a target nucleic acid sequence that is larger than about 100

nucleotides in length;

predicting a folded structure of the target nucleic acid sequence; identifying the nucleotide sequence of a hairpin within the folded structure of the target nucleic acid sequence; and

predicting a folded structure of the nucleotide sequence of hairpin, in the absence of other nucleotides of the target nucleic acid sequence, wherein the folded structure of the hairpin has a predicted E value of at most about – 3 kcal/mol.

- 2. The method according to claim 1 wherein the nucleotide sequence of the hairpin is between about 12 and about 60 nucleotides in length.
- 3. The method according to claim 1 wherein the folded structure of the hairpin has a predicted E value of between about 4 kcal/mol and about 12 kcal/mol.
- 4. The method according to claim 1 further comprising: predicting a folded structure of a duplex formed between the hairpin and its complement.
 - 5. The method according to claim 4 further comprising: determining whether duplex formation is energetically favorable.
- 6. The method according to claim 1 further comprising:

 performing a database search for nucleotide sequences that are similar to the identified nucleotide sequence of the hairpin.
- 7. The method according to claim 6 further comprising:
 determining, from the results of the performed database search,
 whether a clear demarcation exists between scores for target nucleic acid sequences and
 scores for non-target nucleic acid sequences.
- 8. The method according to any one of claims 1-7 further comprising: synthesizing a nucleic acid molecule corresponding to the nucleotide sequence of the hairpin.
- 9. An isolated nucleic acid molecule prepared according to the process of claim 8.
